Abstract
Plant species have long been used as principal ingredients in traditional medicine. Different surveys showed that ethnomedicinal plant species used by the inhabitants of Jordan for the treatment of cancer are inadequately screened for their therapeutic/chemopreventive potential and phytochemical findings. In this mini review, traditional herbal medicines pursued indigenously with their methods of preparation and active constituents are listed. Studies of random screening for selective cytotoxicity and antiproliferative activity of local spices, domesticated greens, or wild plants are briefly discussed. Recommended future directives for the design and conduct of comprehensive trials are pointed out to validate the usefulness of these active plants or bioactive phytoconstituents either alone or in combination with existing therapies or complementing pharmacologies.

Introduction
The Hashemite Kingdom of Jordan’s habitat is unique in that the intersection of dense forest, arid desert, and tropical geography endows the country with a rich variety of plants and microorganisms that can be studied efficiently in a relatively small land area (Fig. 1) [1]. More than 2500 wild plant species from 700 genera exist; of these, there are approximately 100 endemic species, 250 rare species, and 125 very rare species [1–3]. In the Mediterranean basin, there seems to be a wealth of ethnomedical studies providing a new and key tool for a quest after invaluable phytopharmaceuticals or the development of functional foods or nutraceuticals [4–12]. Traditional medicine practices are part of the Jordanian culture. Despite modern medicine accessibility, herbal medicine has often maintained popularity [13]. The percentage of reliability on herbal medicine varies from rural and desert areas to urban ones [14–16]. Crucially, the folk phytotherapy is “aging” or “vanishing” in the sense that knowledge of medicinal plants persists mainly in elderly rural people with little schooling [17]. In the last decades negative human impacts also affected the ecosystem, adding more plants to the list of endangered species, thus calling on the urgent need for community-based programs promoting their national conservation and sustainability [18]. In a survey carried out with the herbalists in Jordan, none of the interviewed herbalists mentioned any plants for the treatment of cancer [15]. On the other hand, literature surveys based on the published studies indicated that in Jordan and in the neighboring countries, 27 plant species are considered as traditional remedies for the treatment of the different types of cancers [14, 19–23]. This article summarizes information on different aspects of chemopreventive-therapeutic plants as well as randomly screened plants for the antiproliferative activity to stimulate interest in these herbs which are of importance in Jordan and other countries of the semi-arid tropics.

Results and Discussion
Cancer is a leading cause of death worldwide. More than 70% of all cancer deaths occurred in low- and middle-income countries. Deaths from cancer worldwide are projected to continue rising, with an estimated 12 million deaths in 2030 [24]. Running second after heart diseases, cancer is a major cause of morbidity among the Jordanian population, with an estimated incidence rate of
5000 new cases per year. Male to female ratio for cancer cases in Jordan is 0.97:1. The overall median age of cancer diagnosis in Jordan is 56 years (males: 60 years; females: 52 years). 43.15% of all newly registered cases occurred in the age of 60 years and above, and 11.6% occurred below the age of 30 years [25].

As recently updated by the Jordan National Cancer Registry (JNCR) statistics, the most commonly diagnosed cancers in a descending order in 2008 would be breast (18.8%), colon (7.7%), lung (7.7%), bladder (4.3%), and non-Hodgkin lymphoma (4.8%) [25, 26].

The evidence-based practices of consuming plants and plant derived products in the treatment of cancer with the orthodox therapy were first reported by Afifi et al. [13]. In cooperation with the King Hussein Cancer Centre (KHCC), the researchers interviewed a total of 1138 randomly selected cancer outpatients, predominantly Jordanians. Among interviewees, the total number of complementary and alternative medicine (CAM) users was 404 (35.5%). All CAM users were either on chemotherapy or radiotherapy and preferred to use the crude extract in the form of infusions (n = 296, 73.3%) [13]. Crude extracts were prepared from coarsely powdered plant mixtures and none of the individual plants could be identified by the researchers. Therefore emphasis is given in the present review to the plants with claimed anticancer activities in the ethnopharmacological studies and to the findings of the random screening of the plant species from the local flora for their antiproliferative activities. Table 1 lists the ethnopharmacologically promoted plants with the method of preparation; parts used and reported phytochemical constituents. Clearly, in half of them, experimental studies to prove their cytotoxicity properties, however unique, are negligible. The majority of the plants (78%), nevertheless, were tested for other pharmacological activities (Table 1).

In an attempt to screen the medicinal herbs from the Jordanian flora collected from each of the four biogeographic regions of Jordan, more than 120 ethanol, chloroform, and water extracts belonging to about 49 families representing 86 genera were evaluated for their antiproliferative activity. Inula graveolens, Salvia dominica, Conya canadiensis and Achillea santolina, L. visciosa, Lavendula officinalis, and S. sylvestris showed promising and potent antiproliferative activities on a breast cancer cell line (MCF–7) [27–29]. The most active plant was *I. graveolens* with an IC$_{50}$ of 3.83 µg/mL [27]. Inclusive reporting of the selective cytotoxicity of *Rhus coriola* and A. biberstenii along with the preceding seven species were collectively presented at the 1st Annual World Cancer Congress 2008 Shanghai, China. The ethanol extracts of the active plants were further evaluated using T47D, ZR-75-1, and BT474 cell lines, as were some of their volatile fractions and isolated pure flavonoids [28]. Al-Kalaldeh et al. demonstrated the cytotoxicity activity for the ethanol extracts of *Origanum syriacum* (IC$_{50}$ of 6.4 µg/mL), *Laurus nobilis* (IC$_{50}$ of 24.5 µg/mL), and *S. triloba* (IC$_{50}$ of 25.3 µg/mL) against MCF-7 cell lines [30]. These were among many other commonly used culinary spices or edible domesticated greens proven for their therapeutic properties [31]. In a parallel line of work, Faris et al. illustrated the enhanced chemopreventive effect of cooked lentils against colorectal carcinogenesis [32]. Furthermore, compared to garlic-only treatment, combined supplementation of soy and garlic had a marked modulation of 7,12 dimethylbenz[a]anthracene induced mammary cancer in female albino rats [33]. Additionally, aqueous extracts of *Nigella sativum*, *Alium sativum*, and *Onopordum acanthium* augmented significantly splenic natural killers’ cytotoxicity against tumor targets in vitro and in vivo [34–36].

Few more reports on selective evaluation of the traditionally used plants for their cytotoxicity activities were obtainable [23, 37, 38]. Talib and Mahasneh screened 16 plants for their antiproliferative activity against Hep–2, MCF–7, and Vero cell lines and demonstrated that methanol fractions of *Ononis hirta* and *L. viscous* exerted their antiproliferative activity by inducing apoptosis in cancer cell lines [23]. In vitro antiproliferative activities of several *Salvia* species against different cancer cell lines were tested by Fiore et al. [37]. Their findings showed promising cytotoxic activity for *S. menthofolia*, *S. spinosa*, *S. sclarea*, and *S. dominica* [37]. In a panel of fibrosarcoma LS293A cells, breast cancer cells MDA-MB231 and MCF–7, organic extracts of *Withania somnifera*, *Psidium guajava*, *L. nobilis*, and *S. fruticosa* also displayed remarkable antitumor cytotoxicity [38]. Withaferin A, a major constituent of *W. somnifera* was further characterized among a novel class of NF–κB inhibitors, holding promise in cancer treatment [39]. As part of serial studies on the unique and under-explored biodiversity of Jordan, the colchicinoids of *Colchicum spp.* (*Colchicaceae*) were pursued [40–44]. Alkaloids of the colchicinoid structural class are well known from this genus, particularly (−)-colchicine, and these compounds have been investigated extensively for both toxicological and potential medical properties, exhibiting potent cytotoxicity against a human cancer cell panel [45]. Nevertheless, the pyrrolizidine alkaloids recovered from *Echium glomeratum* (*Boraginaceae*) by the same research group lacked any anticancerous cytotoxicity [46]. Nowadays, it is well accepted that plant constituents possess cancer-preventive and cancer-therapeutic activities and natural product chemistry has already contributed to 60% of all anticancer drugs [47–49]. Chemoprevention research has gained momentum through the US FDA approval of tamoxifen and raloxifene for breast cancer risk reduction. Various epidemiological and preclinical findings and the results of several early clinical studies convincingly argue for a definitive role of selected dietary products in the treatment and prevention of cancers. Many of these agents target multiple signal transduction pathways; mod-
